

# Project C3S-ISLS - Research Plan

## Influence of Climate Change on Shallow Landslide Susceptibility

### 1 RATIONALE

Shallow landslides imminently endanger human living and infrastructure in mountainous regions of the world. As these areas are often densely populated it is essential to fully understand the processes and variables involved in order to prevent impacts.

### 2 OBJECTIVES

The project aims at determining shallow landslide susceptibility in time and space by means of **statistical and physically-based modelling** with a high degree of automation. Based on **three case studies** the influence of **climate change** on the system status is evaluated. In addition, the effect of **landuse change** on shallow landslide susceptibility is investigated.

Fig. 2: Location of study areas.

### 3 CASE STUDIES

Predisposing factors shall be modelled statistically area-wide within the districts Feldkirch, Dornbirn and Bregenzer Wald in Vorarlberg, Austria. A **landslide inventory** is set up based on semi-automated classification of multitemporal ortho-photos and airborne laser scanning derivatives. In combination with meteorological data this inventory is also used to derive precipitation thresholds for the onset of shallow landslides. The physically-based approach involving the **TRIGRS model**, demanding for detailed knowledge about regolith characteristics, is applied for a slope in the Laternser valley. **Field work** and suited **laboratory tests** yield the necessary geotechnical and hydraulic input parameters. The model is calibrated for past landslide events with known meteorological pre-conditions.

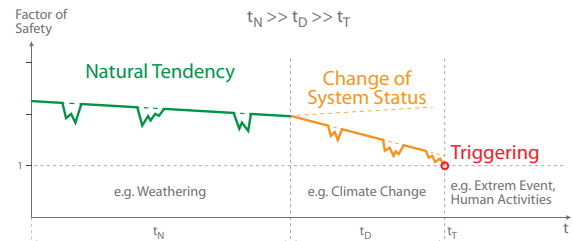

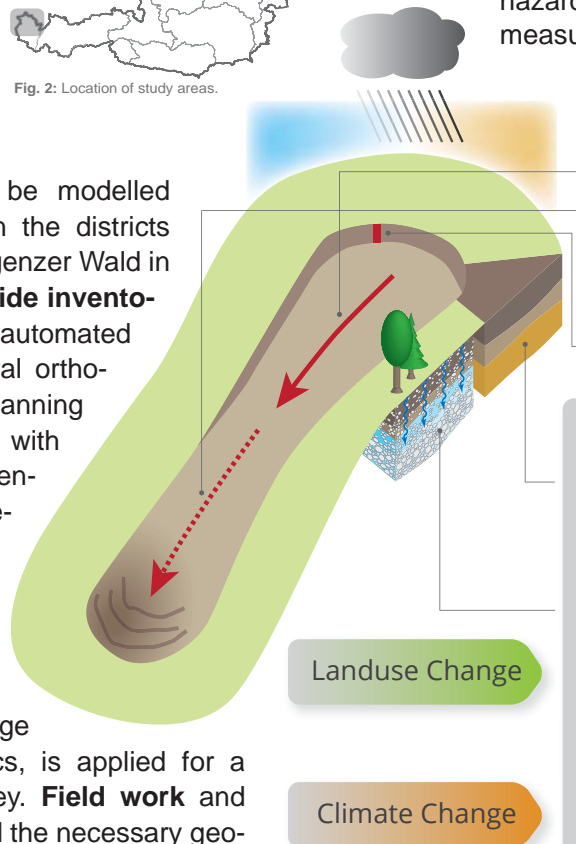

Fig. 3: Concept on changes of the Factor of Safety prior to sliding. Modified after Terzaghi (1950, p. 95).

### 4 RESULTS

In order to quantify the impact of climate change on shallow landslide susceptibility, the results of scenario-based simulations are evaluated against current conditions. In the same way the effects of land use changes are estimated. Finally, potentially affected areas are identified and shown in hazard maps allowing for prevention measures (e.g. spatial planning).

#### PROCESSES

##### Debris Slide - Debris Flow

- Debris: 20 - 80% greater 2 mm
- Translational Slide
- Maximum Depth 1-2 m

#### SUSCEPTIBILITY

- Predisposing Conditions  
*Geology, Topography, Slope, Regolith Characteristics*
- Variable Factors  
*Hydrologic Pre-Condition, Land Cover, Land Use, Vegetation Period*
- Triggering Factors  
*Heavy Rainfall  
Prolonged Rainfall  
Snowmelt*
